Periglacial Geomorphology

Glacial and periglacial geomorphology are those branches of geomorphology concerned with the evolution of landscapes in high latitudes and altitudes. They have been inextricably linked within the history of geomorphology for two principal reasons.

Frost shattering of rocks is common in periglacial environments. Areas of extensive frost shattering can help identify nunataks (isolated ridgetops that extend above glaciers). Extent of periglacial landforms helps to constrain

Periglacial Geomorphology - Hunter College

Periglaciation (adjective: "periglacial", also referring to places at the edges of glacial areas) describes geomorphic processes that result from seasonal thawing of snow in areas of permafrost, the runoff from which refreezes in ice wedges and other structures.

"Periglacial" suggests an environment located on the margin of past glaciers.

Periglaciation - Wikipedia

Definition: Periglacial environments are characterised by frost action and the recurrent presence of a snow cover. If the ground surface consists of sediments, sorted ground phenomena are widespread.

Periglacial environments are areas where landforms and geomorphic processes reflect the cumulative effects of cold subfreezing temperatures, cyclic freezing and thawing of sediments, and the volumetric expansion of soil moisture as it freezes. From: Past Glacial Environments (Second Edition), 2018

Cryogenic (periglacial) processes are a collective term used to describe a set of distinct physical processes related predominantly to freezing and thawing of ground material. Although these processes occur in any area where ground freezes and thaws seasonally, they are most pronounced in areas underlain by permafrost.

Periglacial geomorphology developed in the 1940s–1960s as a branch of climatic geomorphology, focusing first on Quaternary studies and palaeoenvironmental reconstructions, then on current geomorphic activity in cold regions.
